Glossary of Terms

This glossary is to lend definition to commonly used terms contained in the Guidelines for Rail Fastening Assemblies.

*Clip* - A tempered spring steel bar of specific geometric shape designed exclusively to hold the rail to the fastener assembly. It will remain in constant contact with the rail and the fastener assembly. A clip consists of the following parts: toe, heel, center leg, front arch and rear arch. Clips are also referred to as rail clip or resilient spring clip.

*Clip Housing* - A device which provides a hole or tunnel for the center leg of the clip and a seat for the heel of the clip. A clip housing can be any of the following: a tie plate, a weld-on shoulder, an embedded shoulder, DFF assembly or SAS plate.

*Fastener Assembly* - The components required to comprise one rail seat for the purpose of securing the rail to the tie. For concrete ties it consists of the clips, shoulders, insulators and tie pads. For wood ties it is comprised of the clips, tie plates or SAS plates, DFF Assembly and the spikes. Weld-on shoulders can also be part of a fastener assembly.

*Plate Hold Down* - Screw spikes.

*Rail Seat* - The area where the rail is secured to the tie by the fastener assembly.

*Resilient Rail Fasteners* - An assembly consisting of resilient fasteners, an appropriate type of tie plate and plate hold downs used to reduce the track modulus

Also known as - An assembly consisting of one or two cast plates and can be either non-bonded or bonded to provide elasticity. Generally used for vibration and noise attenuation. Also known as a Direct Fixation Fastener.
**Self-Aligning Shoulder Plate** - (SAS) A narrow plate used in pairs which accepts a swivel shoulder to align with the base of the frog, etc. This plate is for use in the area of a turnout where tie plates will not fit. It is generally fastened with screw spikes as the plate hold down and utilizes a cut spike opposite the swivel shoulder to aid in securing the rail.

**SAS Shoulder** - The cast ductile iron clip housing used in conjunction with the Self-Aligning Shoulder Plate which swivels to align with the frog etc....

**Screw Spike** - A threaded plate hold down device which is screwed into the tie.

**Shoulder** - The cast ductile iron insert embedded into the concrete tie. This functions as the clip housing on concrete ties and maintains proper alignment of the components and the rail.

**Spikes** - A cut spike or screw spike used as a plate hold down. Although cut spikes are included in this definition, cut spikes are not recommended for use with wood related resilient fastener assemblies as the primary hold down.

**Tie Pad** - An elastic material in specific shape which can contain geometric patterns to help attenuate wheel loads. The pad’s main purpose is to provide protection for the tie from the forces of wheel loads and other dynamic forces generated by track. Also referred to as a rail seat pad.

**Tie Plate** - A rolled steel, or cast ductile iron clip housing commonly used on canted rail seat generally used on wood ties.

**Weld-On Shoulder** - A clip housing which is cold formed from steel bar. It can also be manufactured as a casting or a forging. WOS’ are engineered for specific applications to insure proper clip deflection.
